

# **Variables**

#### boolean Data Type

In Java, the boolean primitive data type is used to store a value, which can be either true or false.

#### **Strings**

A String in Java is a Object that holds multiple characters. It is not a primitive datatype.

A String can be created by placing characters between a pair of double quotes ( " ).

To compare Strings, the equals() method must be used instead of the primitive equality comparator \_\_

### int Data Type

In Java, the int datatype is used to store integer values. This means that it can store all positive and negative whole numbers and zero.

#### char Data Type

In Java, **char** is used to store a single character. The character must be enclosed in single quotes.

#### **Primitive Data Types**

Java's most basic data types are known as *primitive* data types and are in the system by default.

The available types are as follows:

- · int
- char
- boolean
- byte
- long
- short
- double
- float

null is another, but it can only ever store the value null.

```
boolean result = true;
boolean isMarried = false;
```

```
// Creating a String variable
String name = "Bob";

// The following will print "false"
because strings are case-sensitive
System.out.println(name.equals("bob"));
```

```
int num1 = 10;  // positive value
int num2 = -5;  // negative value
int num3 = 0;  // zero value
int num4 = 12.5; // not allowed
```

```
char answer = 'y';
```

```
int age = 28;
char grade = 'A';
boolean late = true;
byte b = 20;
long num1 = 1234567;
short no = 10;
float k = (float)12.5;
double pi = 3.14;
```

#### **Static Typing**

In Java, the type of a variable is checked at compile time. This is known as *static typing*. It has the advantage of catching the errors at compile time rather than at execution time.

Variables must be declared with the appropriate data type or the program will not compile.

### **Math Operations**

Basic math operations can be applied to int, double and float data types:

- + addition
- subtraction
- \* multiplication
- / division
- % modulo (yields the remainder)

These operations are not supported for other data types.

## **Comparison Operators**

Comparison operators can be used to compare two values:

- > greater than
- < less than</li>
- >= greater than or equal to
- <= less than or equal to</li>
- == equal to
- != not equal to

They are supported for primitive data types and the result of a comparison is a boolean value true or false.

## code cademy

```
int a = 20;
int b = 10;

int result;

result = a + b;  // 30

result = a - b;  // 10

result = a * b;  // 200

result = a / b;  // 2

result = a % b;  // 0
```

```
int a = 5;
int b = 3;

boolean result = a > b;
// result now holds the boolean value
true
```
